In the packaging of certain loads, it is desirable to confine heat generated by an electrical load inside the load. Such electrical loads may include, for example, a lamp, a load associated with a microprocessor, etc. Typically, lamp loads in certain lighting systems utilize a resistive load bulb. In some instances, it is desirable to provide heat to the load without substantially adversely affecting or modifying the light emitted from the load. For example, if the light emitted from a resistive load bulb becomes an intense light source, such as when the lamp load fails to turn off after it is initially turned on, the potential exists to cause damage to persons or property in the vicinity of the load. Accordingly, it is desirable to provide a means for dissipating excess heat generated by the resistive load bulb during a period of time after power has initially been applied to the bulb. It is known, for example, to mount a resistive load bulb on an enclosed heat sink having a central bore extending through the heat sink. The heat sink can be surface-mounted directly upon a circuit board to which the load is electrically connected, or can be attached to a heat sink embedded in a circuit board. A space is disposed within the

What's new in Craft The World - Heart Of Evil:

Menu Tag Archives: annie wood The field of quantum physics has made a leap of immeasurable proportions in recent years. Many years ago the trick to understanding the singularity of black holes was to think of them as organizing quantum states in a Hilbert space, with elements of that Hilbert space corresponding to the (quantum) microstates of a black hole, and time as nothing but an important coordinate to compute the evolution of the state. Recent work on describing black hole entropy dates as far back as 1985, and deals with the fundamental math that describes how information is reconciled with black hole entropy. In this new approach to quantum mechanics, the classical concept of a point particle is replaced by

something that is analogous to a gas, with its characteristic statistical uncertainty and concentration. The two main models of quantum gravity, loop quantum gravity and string theory, diverge only at the Planck scale, where the size of space-time is on the order of the Planck length. Conventional general relativity must be replaced by a new version of classical gravity at this scale, where the classical description of relativistic theory fails. In two papers co-authored with colleagues at Northeastern, MIT, and Peking University, and published in Physical Review Letters, Princeton researchers extend results on cosmic microwave background fluctuations from the Planck satellite. In the first paper, the researchers confirm some large-scale characteristics of the fluctuations, which were detected first by NASA's COBE satellite and have previously been confirmed by ground-based instruments. The researchers also present new measurements using data from the Planck satellite. The new data set provides even more precision and extends Planck's measurements out to greater distances, in more detail, and at higher wavelengths, helping to pin down the cosmic structure behind the fluctuations. The paper

describes two primary anomalies in the smooth cosmic background radiation (CBRA). One occurs on large angular scales of the order of a full Hubble angle, exhibiting itself as a temperature irregularity. The other displays itself as a set of oscillations on smaller angular scales, and is referred to as the “acoustic signatures.” Unlike the first anomaly, which has been widely reported and measured, the acoustic signature is only now beginning to be measured in detail. “Overall the cosmic background radiation presents us with an amazing map of the universe, and the Planck mission’s mission was to refine measurements and to extend the measurements as far as possible,✦
